Peak integration

- Integration in GMP laboratories is critically important
 - has become focus of data integrity-centric regulatory inspections
- Data systems developed for chromatograms rather than electropherograms, and the increased regulatory scrutiny call for a resolution.
- This extends to R&D, clinical, and academic labs

Tim Blanc, Hermann Wätzig and Cari Sängler – van de Griend,
Peak Integration of Electropherograms in GMP and Research Labs:
Navigating Increased Scrutiny Amid Data Integrity Audits and Inspections

Peak integration: Conclusions from this review

- We need APs and SOPs
- We need detailed method descriptions, defaults, parameter lists, illustrations, training
- We need to keep manual integration at the present time
- Collaboration within the industry for generally accepted standards
- Benchmark data sets could be an important step
- Based on this, considerable improvements in integration algorithms are possible
- So probably less manual integration in the future, but at present it is still a must

Peak integration: Conclusions from this review

- We need APs and SOPs
- We need detailed method descriptions, defaults, parameter lists, illustrations, training
- We need to keep manual integration at the present time
- Collaboration within the industry for generally accepted standards
- **Benchmark/Reference data sets could be an important step**
- Based on this, considerable improvements in integration algorithms are possible
- So probably less manual integration in the future, but at present it is still a must

Debatable and context-dependant cases

- Is circle marked area a peak or noise?
- If peak: Which approach is better?
- Should square marked points be integration limits due to the comparison to the left image section?

com2-type2-sam2

- Does the marked area belong to the baseline or does it lay above and therefore form a peak?

com2-type2-sam25 and com2-type2-sam5

- Are there any peaks to be considered between the main peaks or is it just noise?

com2-type2-sam25 (top) vs. com2-type2-sam5 (bottom)

- Are there any peaks to be considered between the main peaks or is it just noise?

Suggestion, related to the European Pharmacopoeia 2.2.47, Capillary Electrophoresis:
Find baseline as close as possible to the possible peaks of interest, 20 times as long as a major peak's $h_{0.5}$, estimate peak-to-peak noise. All signal $S/N > 3$ considered as peaks

Abstract

Capillary electrophoresis (CE) often offers superior separation relative to chromatography for macromolecules like monoclonal antibodies (mAbs), a major pharmaceutical class. However, electropherogram baselines pose challenges that traditional chromatography integration algorithms cannot address, necessitating complex integration processes [1]. There are numerous ideas for improving peak integration, ranging from simple algorithms to improve the S/N ratio to more sophisticated AI solutions. However, none of these can demonstrate that they are genuine improvements, as they cannot be compared with each other or with previous algorithms using the same reference datasets. This is why a multinational collaboration between industry and universities was initiated. Data sets were collected, brought into a standardized format and then integrated by teams of experts. Once all the experts have reached a consensus on reasonable peak boundaries, this consolidated data is now available to the scientific public.

Discussions among the experts have revealed, that the used zoom factor appears to have a notable influence on the way people integrate, emphasising the necessity of its documentation and standardisation.

Conclusion

- By the end of the collaboration, we will publish a total of over 229 electropherograms with approved reference peak boundaries.
- To ensure comprehensibility, we recommend the documentation of the zoom level currently applied whenever manual integration is carried out, as well as the utilisation of pre-defined focus factors.
