Introducing the iSKID™

An integrated approach to manufacturing

The iSKID™ initiative is a technology partnership between Pfizer and Boehringer Ingelheim (BI) focused on delivering transformative manufacturing efficiency and accelerated launch options for protein therapeutics (drug substance/DS).

A Typical mAb Platform Process

Poor resin utilization during clinical manufacture

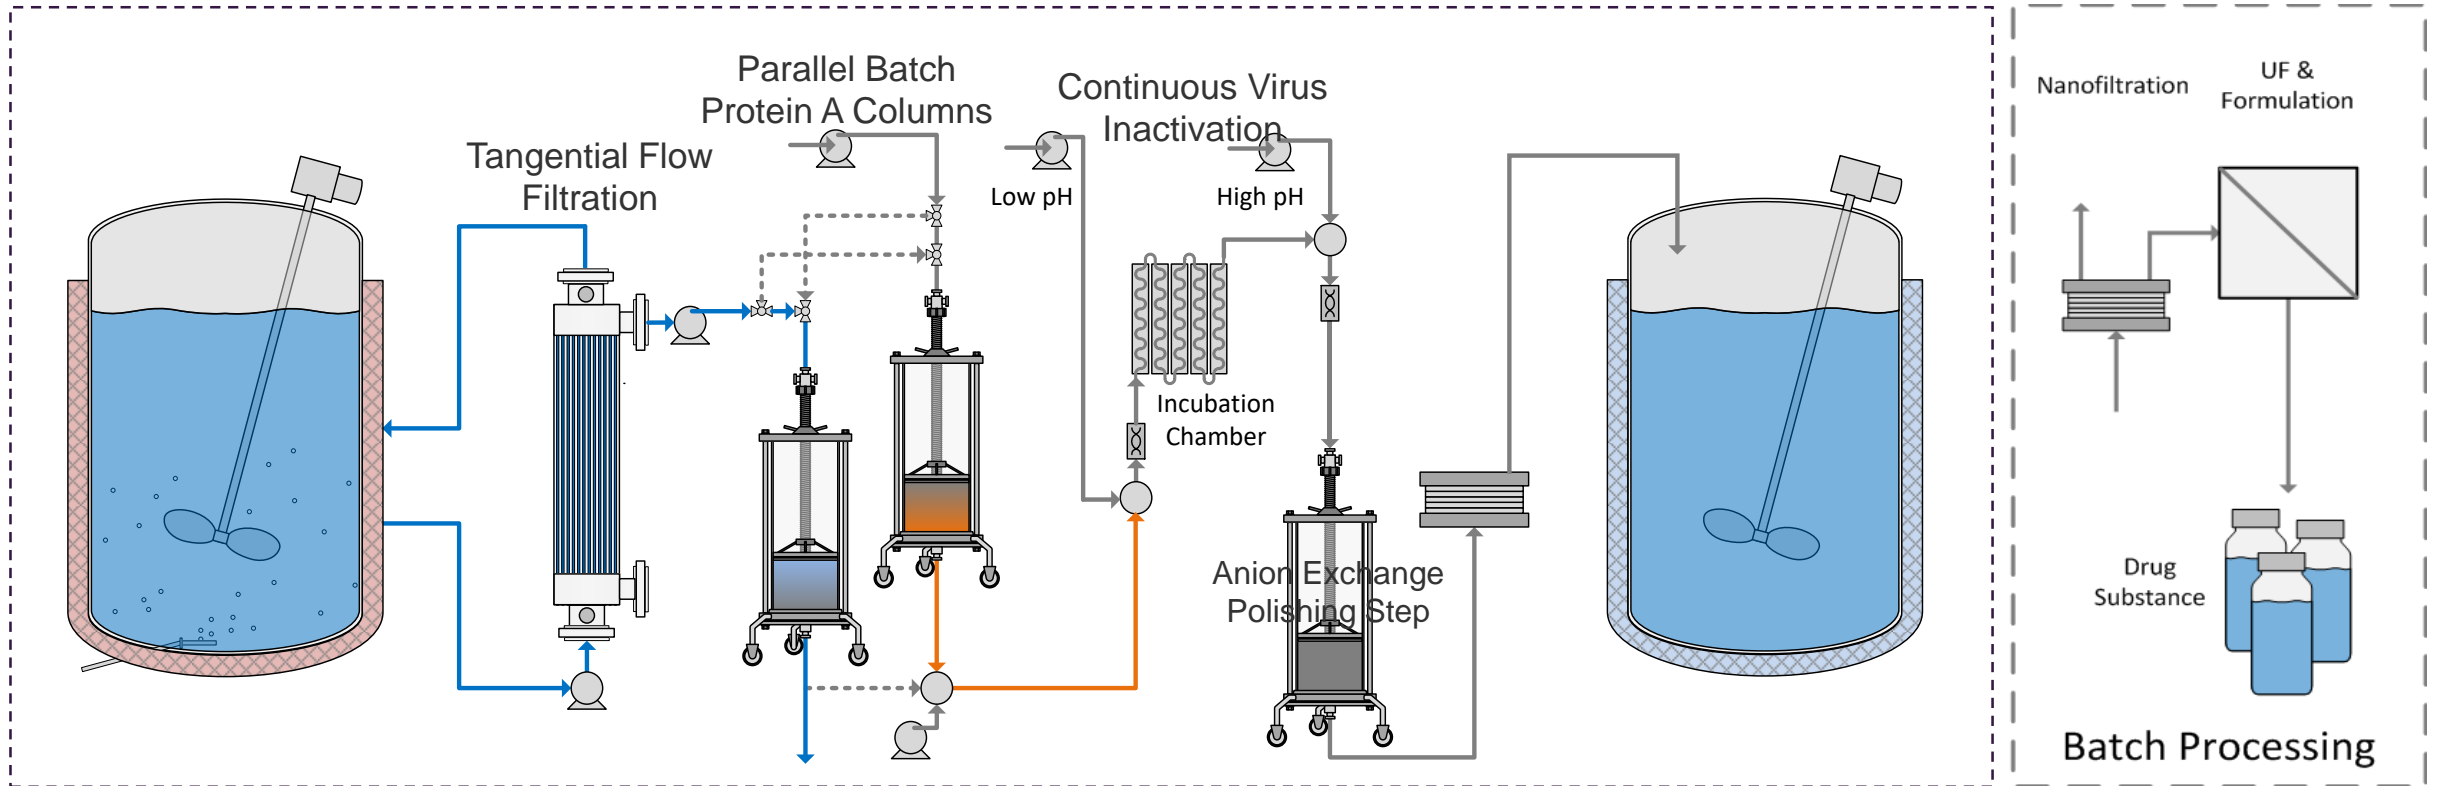

A single bioreactor leaves the downstream idle 7-13 days out

Lots of space for holds and buffers

iSKID™ Integrated Manufacturing System

Thoughtful integration of process maximizes productivity

- Fully automated and disposable system
 - Highly productive short duration perfusion: 2-3 week cadence
 - “Simple” downstream design – Continuous, periodic, batch
 - Buffer and media concentrates

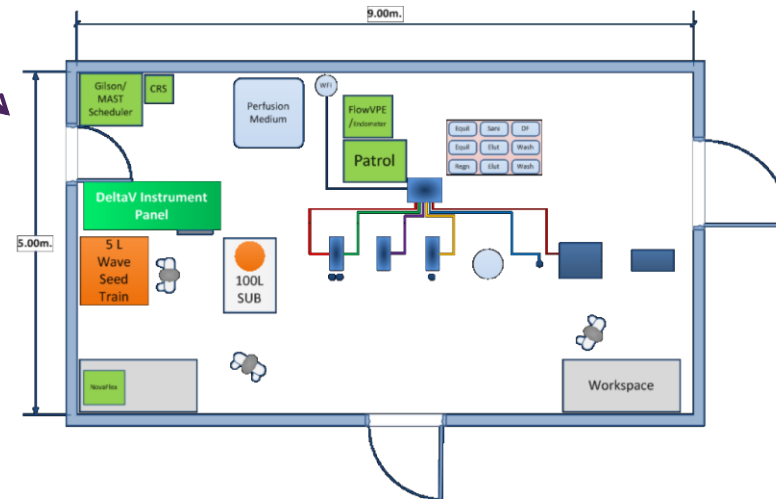

Re-Imagining Bio-Manufacturing

Current state of the art
Clinical manufacturing facility

Future State: iSKID

Cumulative 100L SUB Production: Output Can Exceed 2 kg of mAb in Permeate

Development and Prototype Runs Average Cumulative Production in Perfusion Permeate

- Significant reduction in media via concentrates
- No loss from bleed – product yield savings

- Demonstrated volumetric productivity*: 1-4 g/L/day
 - 3-4x productivity increase over optimized fed-batch processes
- *calculated from day 0*

Short duration perfusion integrated with simple, two column continuous capture

- Removed product from the bioreactor faster
- Better downstream utilization
- Accommodates variability and wide range of upstream conditions
- Fully automated continuous two column harvest: simple operation, easy development, better Protein A utilization

Periodic stage intensifies polishing operations by relying on robust development history

Periodic Stage

Periodic stage intensifies polishing operations by relying on robust development history

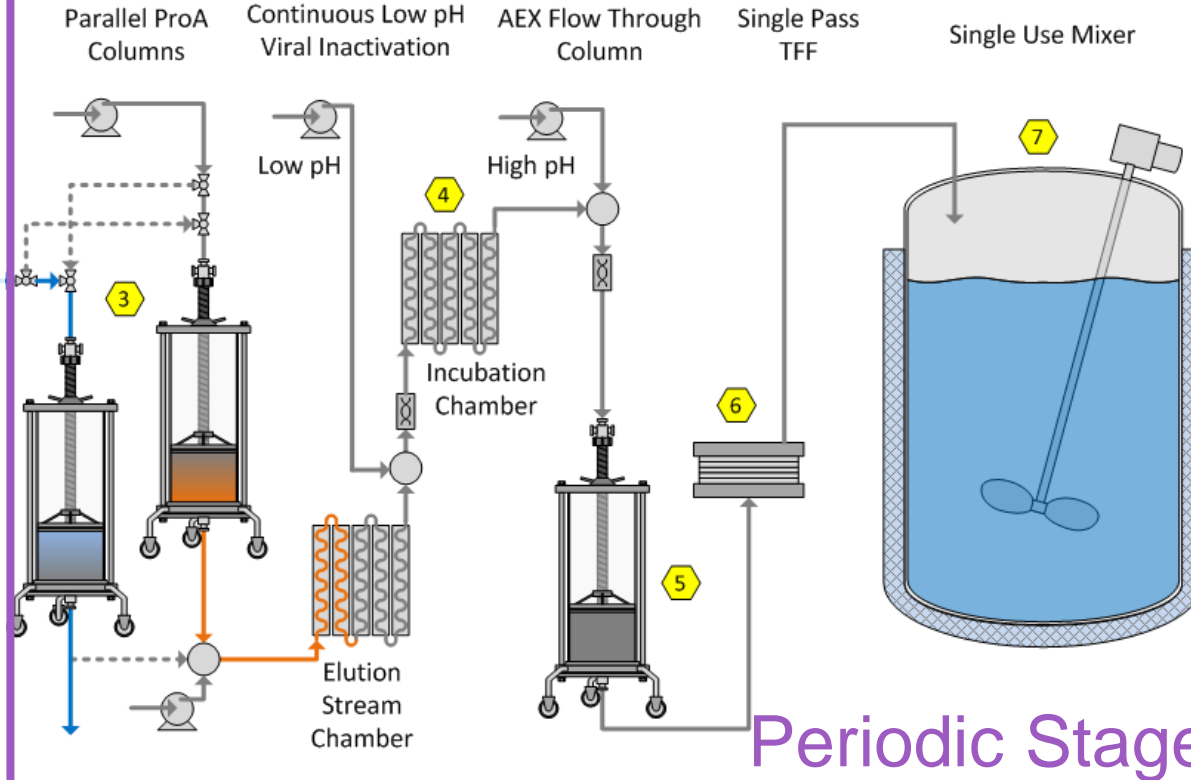

- Eliminates in-process holds
- Process development can leverage rich batch experience

Tangential Flow Filtration

Feeds

Integrated Continuous Processing

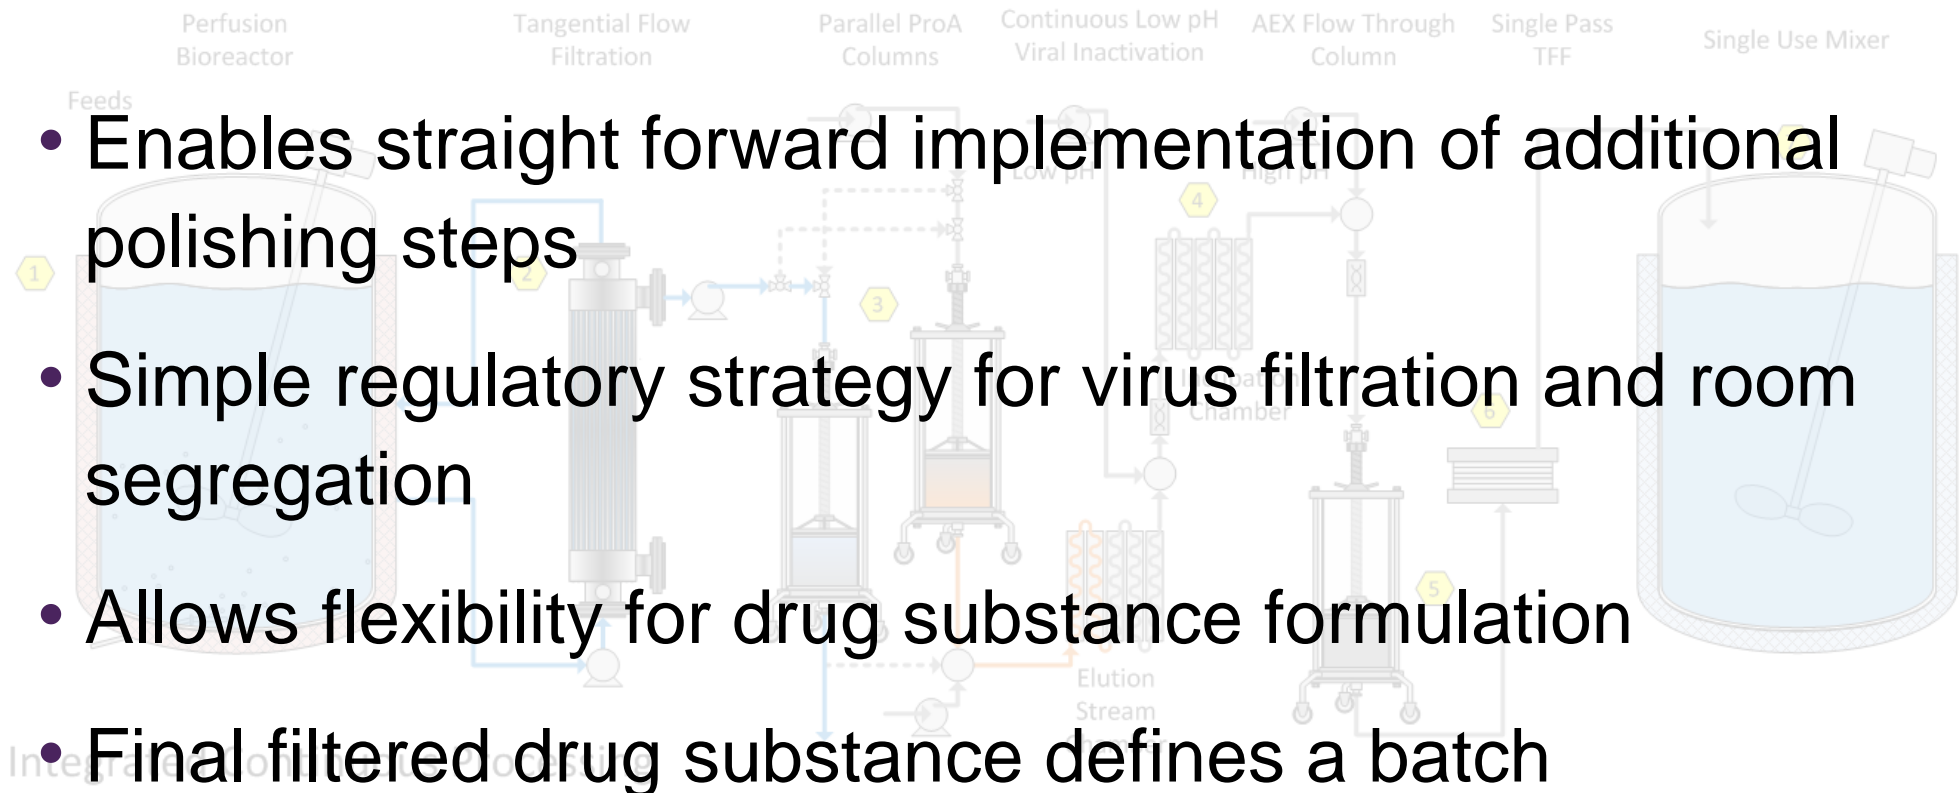

Nanofiltration

UF & Formulation

Batch Processing

Batch Stage reduces regulatory risks and provides flexibility

- Enables straight forward implementation of additional polishing steps
- Simple regulatory strategy for virus filtration and room segregation
- Allows flexibility for drug substance formulation
- Final filtered drug substance defines a batch

Batch Stage

What Does it Look Like?

Current Development Paradigm

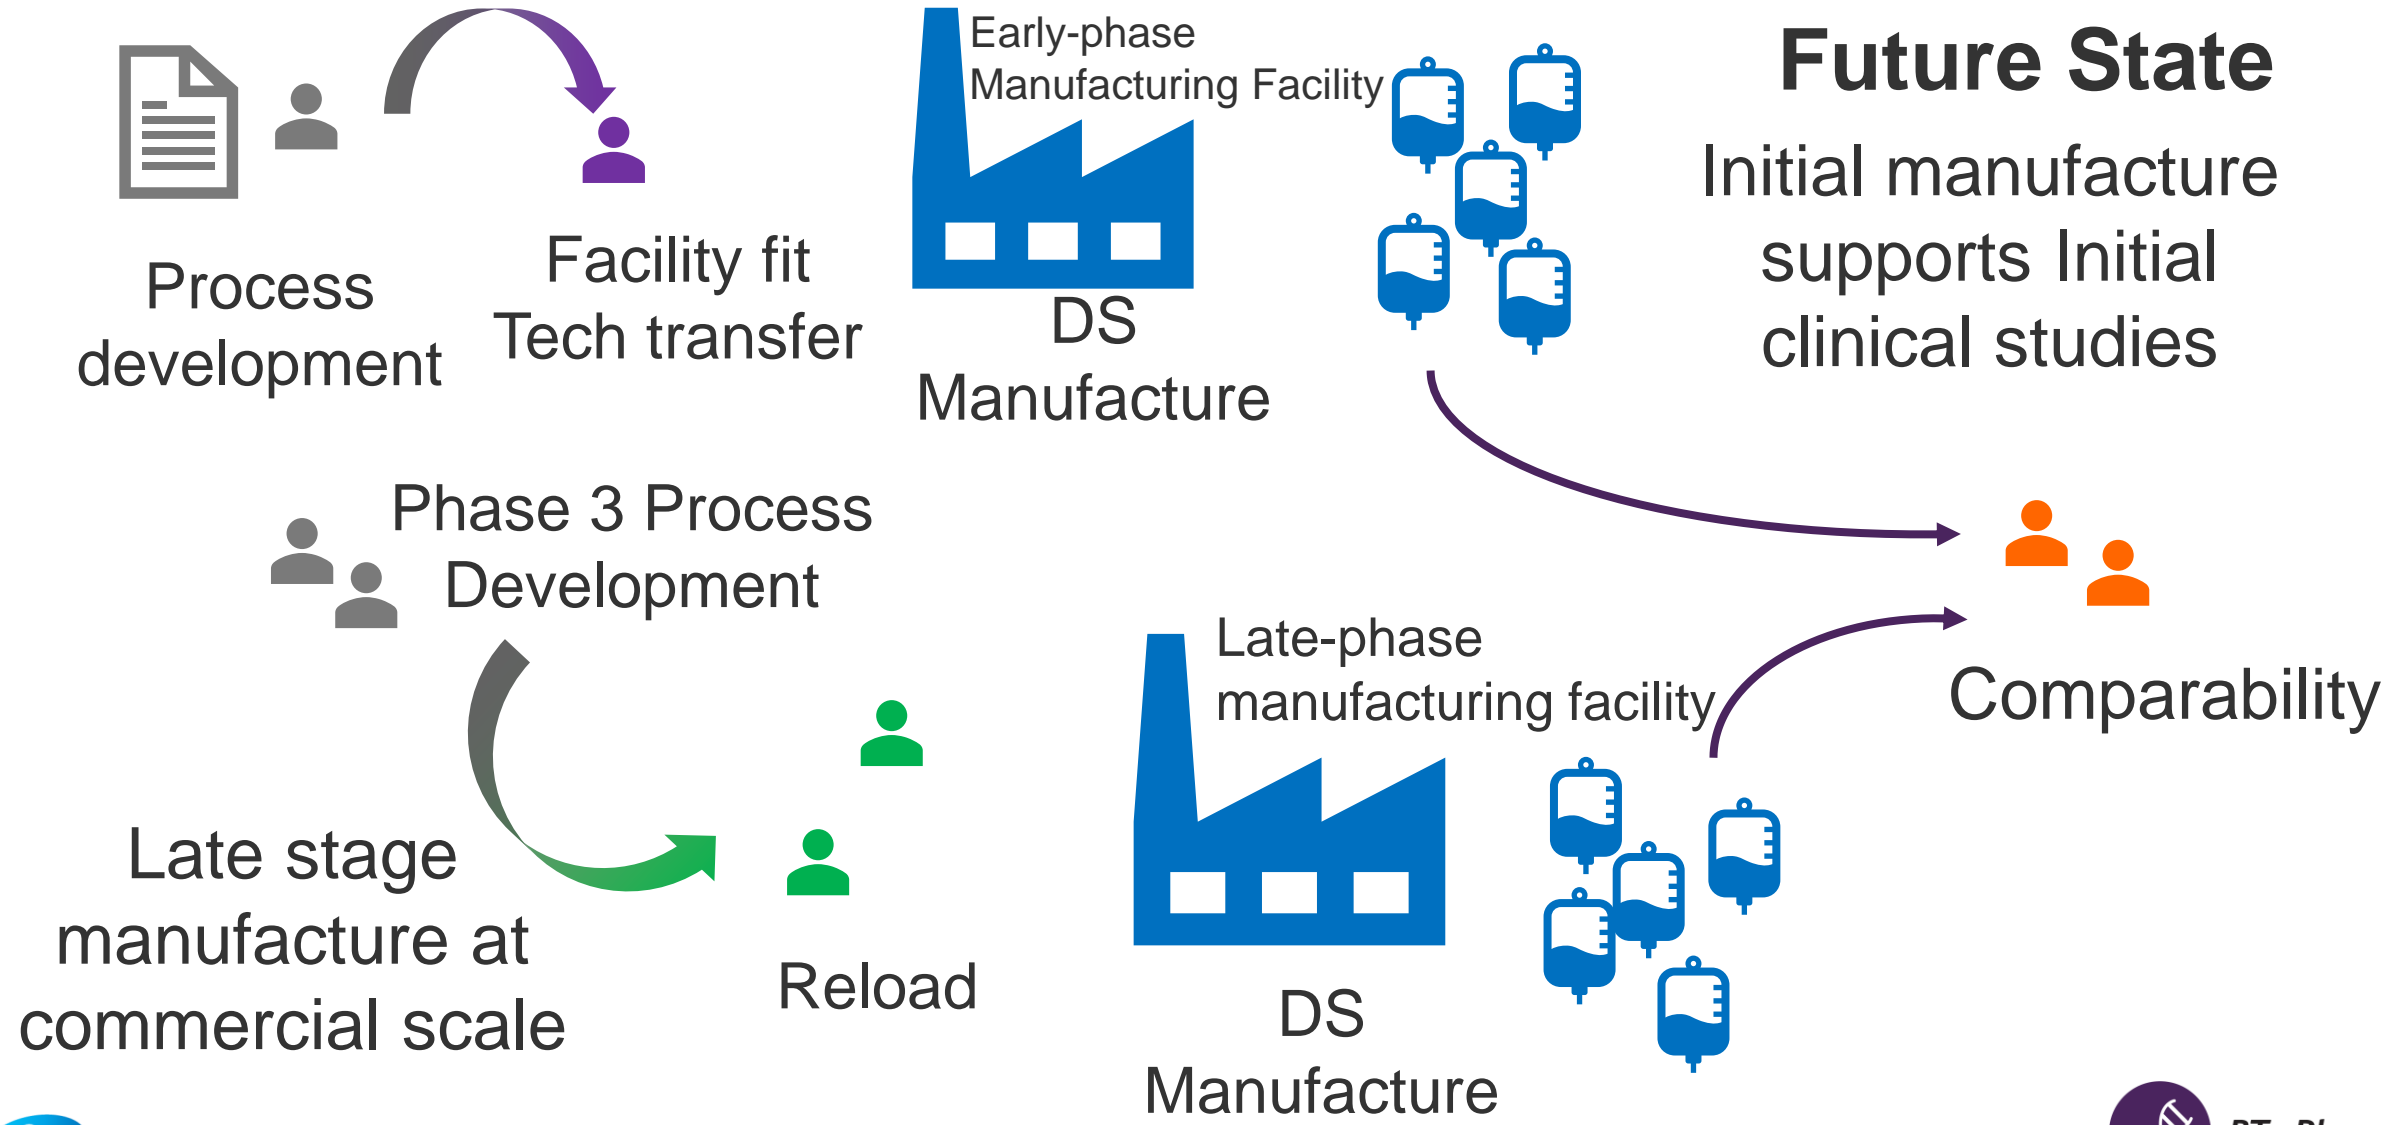

Current State

Initial manufacture supports early clinical studies

Comparability

iSKID™ Development Paradigm

Current hardware design supports multiple scales

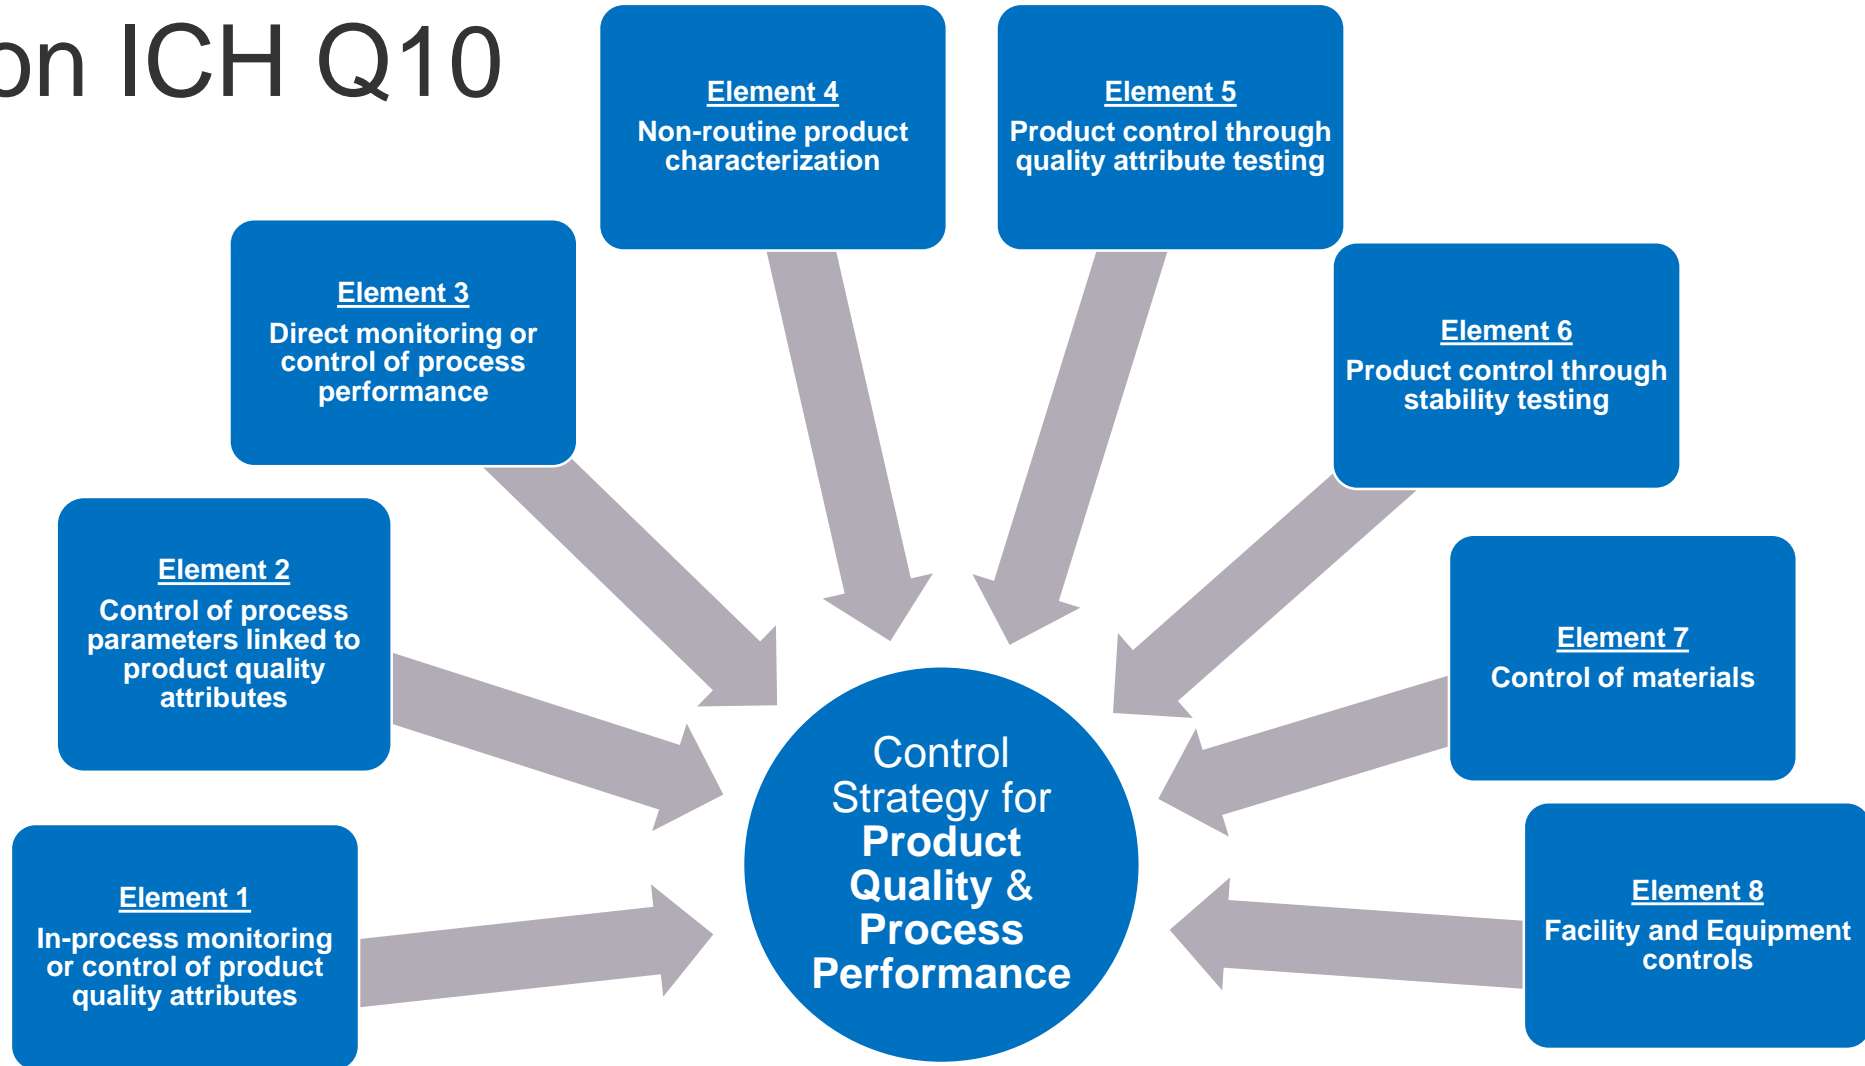

- Scale columns and disposable flow paths

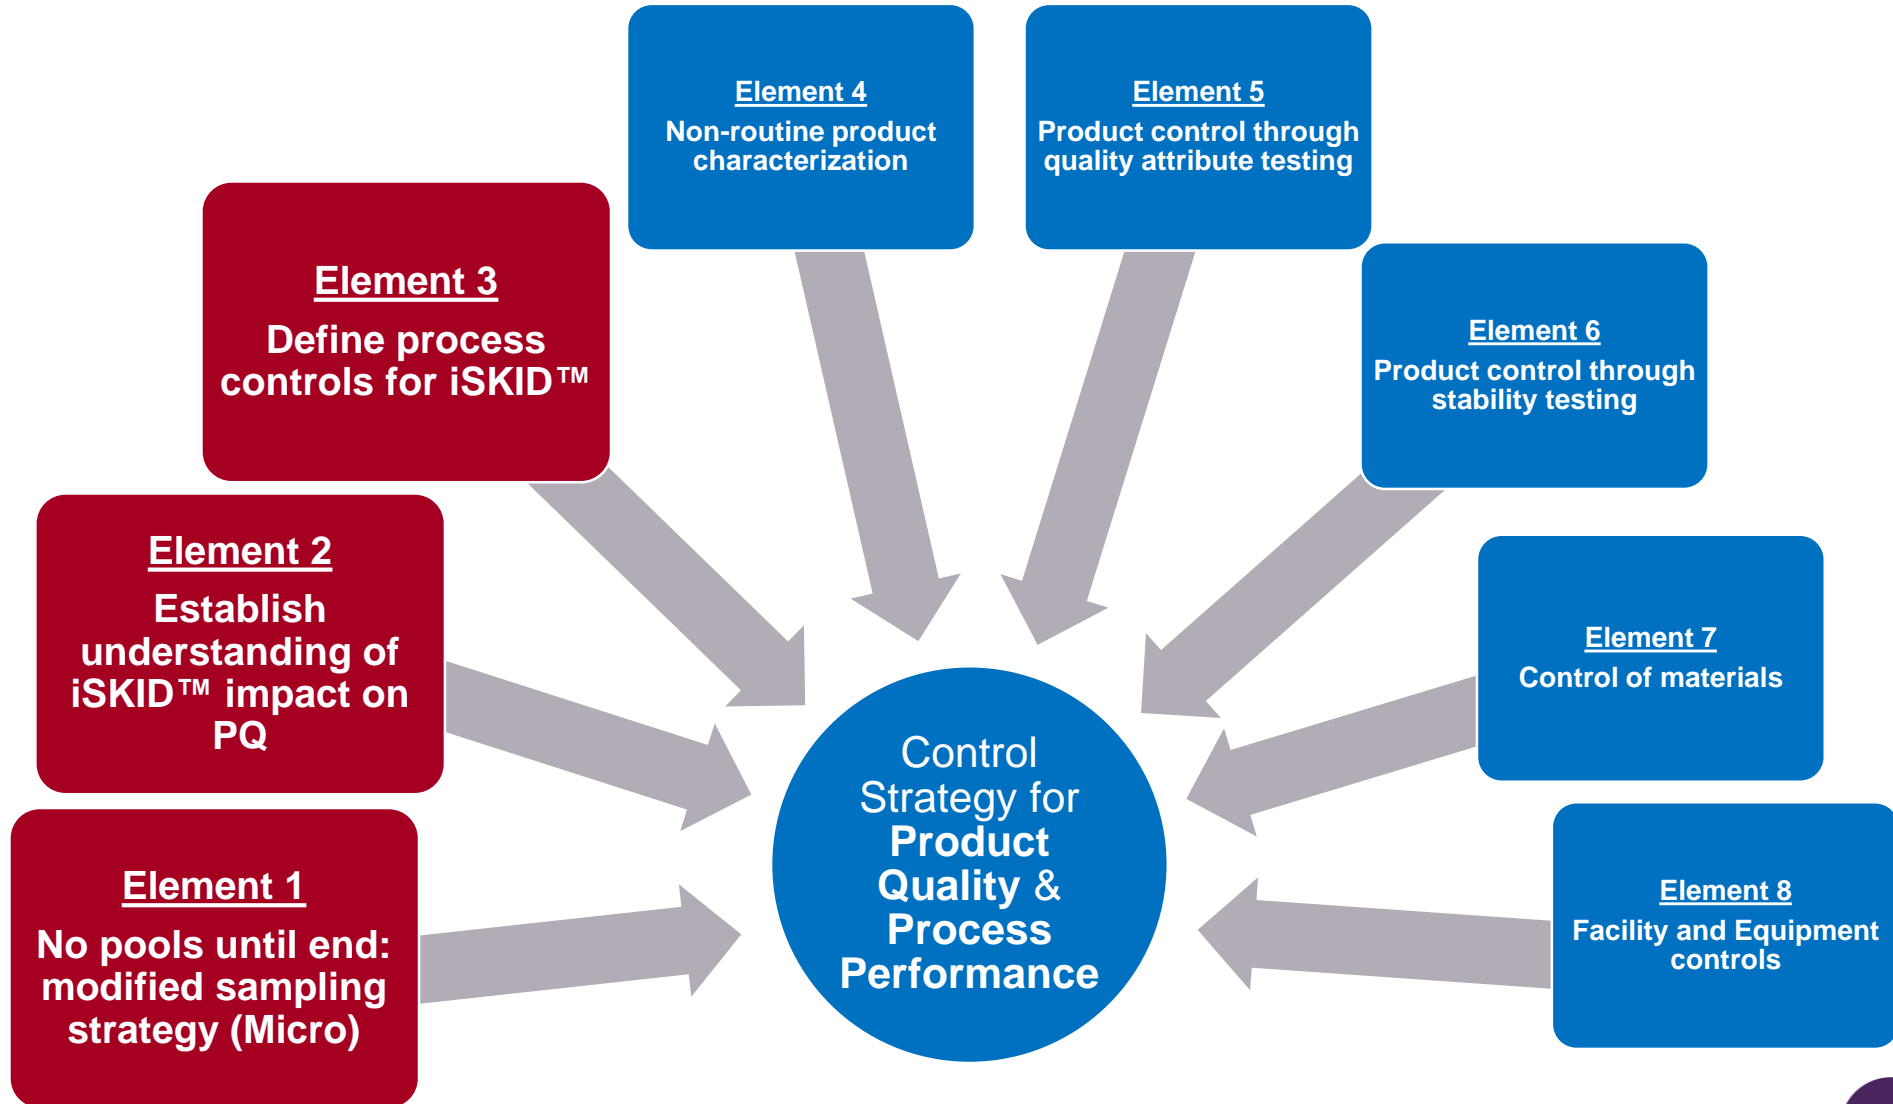

How Does iSkid Design Impact Control Strategy?

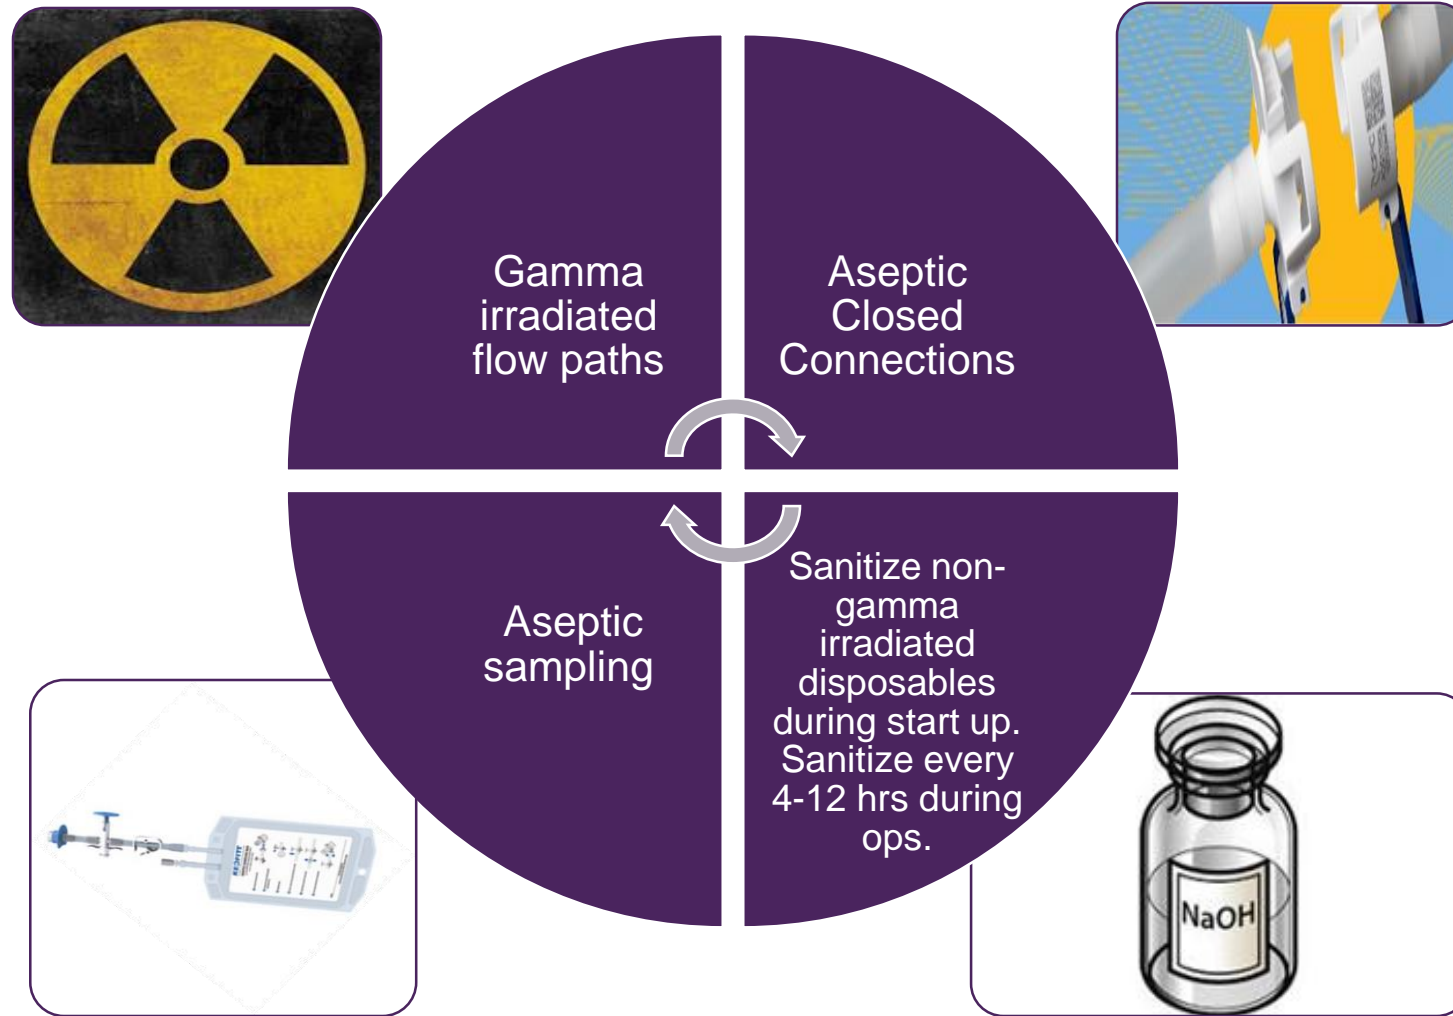

Based on ICH Q10

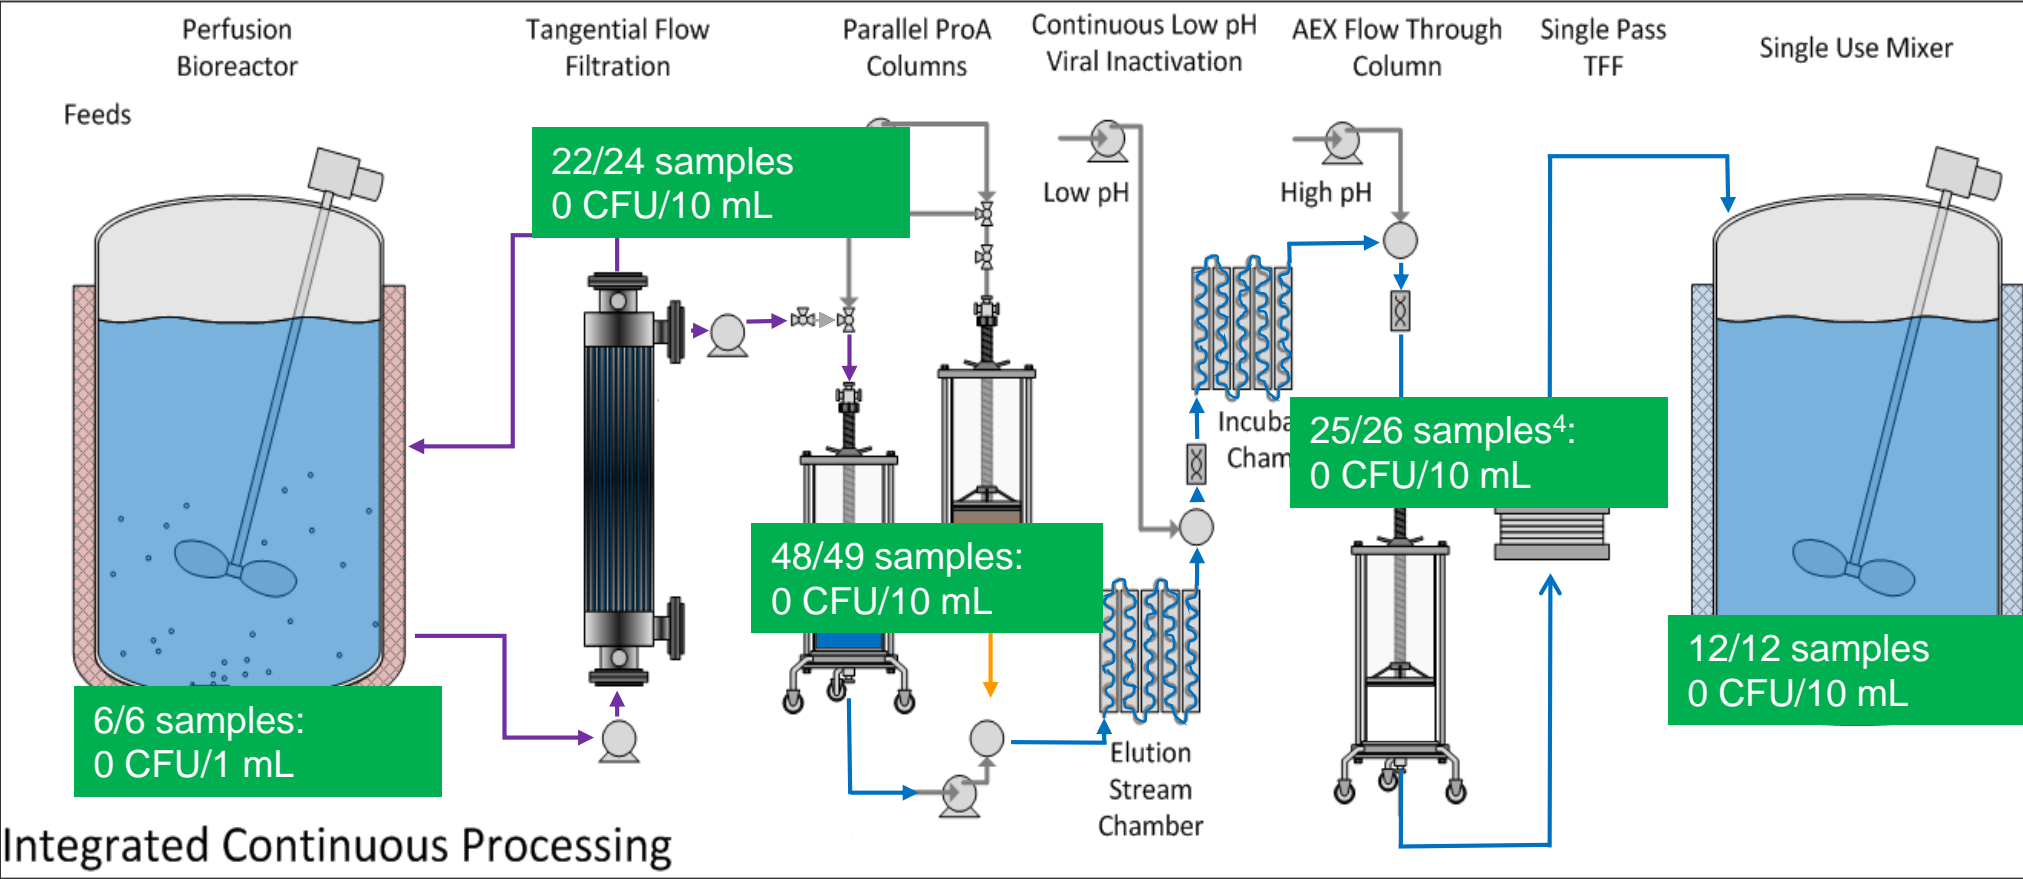

iSKID™ Will Require a Modified Control Strategy

Bioburden control- mitigation strategy

Bioburden Data: Prototype System Consistency Runs at STL & AND (6 total)

Drug Substance
All samples (6/6)
No growth

- Samples with growth were all low level (≤ 3 CFU/10mL), well within non-GMP in-process expectations

Note: All endotoxin data passed ≤ 2 EU/mL

iSKID™ Summary

- Represents a successful collaborative initiative between Pfizer and BTx
- **iSKID™ expands development and manufacturing capacity**
 - Short duration perfusion: highly productive and efficient
 - Simple downstream process: easy to develop and control
- **Appropriate for low volume, high value products**
- **Scalable to accommodate increase in demand**
- **Enhanced Cost & Capacity Profile**
 - Facility friendly
- **Integration and automation facilitates improved operational excellence**
